ABSTRACT

Color image restoration is one of the basic tasks in pattern recognition. Unlike grayscale image, each color image has three channels in the RGB color space. Due to the inner-relationship within the three channels, color image restoration is usually much more difficult than its grayscale counterpart. Indeed, new problems such as color artifacts could emerge when the grayscale image processing methods are extended to color images directly. Note that one of the most effective gray image restoration methods is the weighted nuclear norm minimization (WNNM) approach. However, when applied to color images, the results of WNNM are usually not as promising as that of grayscale images. In order to solve this problem, in this paper, we propose to restore color images with the quaternion-based WNNM method (QWNNM) since the structure of color channels can be well preserved with quaternion representation. The proposed model can be solved efficiently by the alternating direction method of multipliers (ADMM). The theoretical analysis of the optimal solution is also presented. Numerical experiments are carefully conducted with different kinds of degradation to illustrate the superior performance of our proposed QWNNM over the state-of-the-art methods, including a celebrated deep learning approach, in both visual quality and numerical results.

1. Introduction

Color images corrupted by blur and noise are unavoidable in the process of image storage and transmission. Given the rapidly growing role of color images in daily lives, color image restoration has become a popular research field. In the literature, remarkable efforts have been put to recover color images from their corresponding degraded ones, such as the variation-based methods [1], the dictionary-based methods [2], and the convolutional neural network-based methods [3,4], etc. Most of the above methods are to handle the color image in the real number domain [5]. It is well known that color images consist of three color channels (red, green, and blue in the RGB color space) with inner-relationships among them [6]. If the three color channels in the real number space are treated as three stand-alone matrices [7], the negligence of the inner-relationship among color channels is inevitable. Recently, due to its capability of well preserving the structure

of channels, the quaternion representation [8] has been widely used in color image processing. For instance, Subakan and Venmuri [9] presented color image smoothing and segmentation with the quaternion framework. Li et al. [10,11] handled the color image denoising task with the quaternion-based non-local total variation and non-local means. Chen et al. [12] and Yu et al. [13] denoised color images with quaternion-based low-rank regularizer. Shi et al. [14] proposed a color histopathological image classification method based on quaternion Grassmann average network. Quaternion neural networks were also applied to image denoising [15] and classification [16]. However, color image deblurring in the quaternion domain remains a challenging problem. The difficulty of the task lies in how the blurring operator is dealt with. In the quaternion domain, the special multiplication rule makes the deblurring task even harder. Restoring color images in the quaternion domain directly is still a big challenge and an open question. As far as we know, Jia et al. [17] proposed a color image restoration model based on quaternion by transforming the color image into the HSV color space instead of handling the quaternion representation directly. In this paper, we propose a new quaternion-based

color image restoration method. To solve the proposed model directly in the quaternion domain, we design a special quaternion blurring matrix.

Restoring a color image from the corresponding corrupted one is usually complicated [18,19]. Due to the fact that the high-dimensional matrix inherently has a low-rank structure [20], restricting the underlying image matrix to be low rank is often a better approach [21]. The low-rank image restoration methods usually outperform methods based on nonlocal and block-matching and 3D filtering (BM3D) [22]. The nuclear norm minimization (NNM) is a common convex surrogate to the rank minimization problem. The NNM method treats every singular value equally, which means that it posits all the singular values contain the same information, regardless of their sizes. However, many works [23,24] have pointed out that the larger singular values carry more data, which explains why the NNM yields only sub-optimal results. Gu et al. [25] proposed a method based on weighted nuclear norm minimization (WNNM) which assigned a weight to each singular value for grayscale image denoising. In 2016, Gu et al. [23] extended the application of the WNNM method, including grayscale image denoising, background subtraction, color image inpainting, and color image denoising. In the results of the image denoising schemes, an interesting phenomenon is observed, namely that some color spots remain in the denoising results of color images, while the grayscale images have almost perfect results. Interested readers may look up the reference [23] (Fig. 5) for details.

The underlying difference between color and grayscale images is the color channels. If color images are denoted as the combination of grayscale images, the inner-relationships between different channels will be totally ignored [26]. Moreover, it is not reasonable to handle the color image with a low-rank approximation method by representing the color image as the linear combination of grayscale images. The three grayscale images that correspond to each channel have different singular value matrices. When we only consider these singular values, the correlation between the three matrices is not taken into account. Whereas representing the color image as a pure quaternion matrix, all we need is to deal with a quaternion singular value matrix. The relationship between the color channels can also be well utilized, hence the degraded image can be better restored [27]. Given the similarity between the three color channels in color images and the three imaginary parts in pure quaternion matrices, we represent color images with pure quaternion matrices [28] in this paper. On the other hand, quaternion matrices have a special multiplication rule, which can be exploited to better present the internal structure of color images [29]. Many researchers have presented theoretical analyses of the quaternions. Quaternion Fourier transform was studied in [30]. Zhang gave some brief proofs of theories on quaternions and quaternion matrices [28]. The theory of quaternion matrix derivatives was studied in [31]. In 2017, Jia et al. [32] presented the theory of the quaternion-based principal component analysis. Later,

Chen et al. [33] incorporated the singular value decomposition into the quaternion domain. Qi and Zhang [34] extended the theory of complex number domain into quaternion domain. These rich mathematical tools grant us theoretical guarantees when quaternion representation of color images is used.

To ensure the color image restoration tasks can be well implemented, we represent the color image with a pure quaternion matrix. A preliminary result of the proposed model is displayed in Fig. 1. To better demonstrate the visual quality and numerical results of the proposed model, we compare our model with the convolutional neural network-based method IRCNN [35]. From the restoration results, we can see that the quaternion representation is better than the real-valued ones, even if it is a CNN-based method. Different from existing color image restoration methods, our main contributions are as follows.

- We develop the classical WNNM method to the quaternion domain for color image restoration. We encode the color image as a pure quaternion matrix, such that more interconnected information among the RGB channels can be preserved.
- To better recover the color image in the quaternion domain, we extend the 2-dimension blurring matrix to the quaternion domain and design a quaternion blurring operator.
- We solve the proposed model efficiently by the ADMM method and the theoretical analysis of the uniqueness of the solution is also presented.
- Experiments show that the proposed method outperforms some state-of-the-art methods, including the CNN-based method.

The outline of this paper is as follows. Section 2 reviews the basic concepts of quaternion algebra and the classical WNNM method. Section 3 presents the proposed model and theoretical analysis. In Section 4, numerical experiments and results are presented and reported. Finally, we conclude our paper in Section 5.

2. Related concepts

2.1. Quaternion

Let \mathbb{R} be the real number space with real numbers denoted by a , and \mathbb{H} be the quaternion space with quaternions denoted by a . The quaternion was first introduced by Hamilton [8]. Suppose a is a quaternion, then it can be written as

$$a = a_0 + a_1 i + a_2 j + a_3 k, \quad (1)$$

where $a_0, a_1, a_2, a_3 \in \mathbb{R}$ and i, j, k are the fundamental quaternion units which satisfy the quaternion rules $i^2 = j^2 = k^2 = ijk = -1$. More specifically, the $ij = k$, $jk = i$, $ki = j$, $ji = -k$, $kj = -i$, $ik = -j$. Form $ij = k$, we know that $ijk = kk = k^2 = -1$ [8]. Let $a = a_0 + a_1 i + a_2 j + a_3 k \in \mathbb{H}$, $b = b_0 + b_1 i + b_2 j + b_3 k \in \mathbb{H}$, and

Fig. 1. Color image restoration on Img26 with visual quality and numerical results (PSNR/SSIM). (a) Original image, (b) degraded image with motion kernel (20, 60) and Gaussian noise level $\sigma = 25$, restored image reconstructed by: (c) IRCNN [35], (h) Our QWNNM.

$\lambda \in \mathbb{R}$, then we have

$$\dot{a} + \dot{b} = (a_0 + b_0) + (a_1 + b_1)i + (a_2 + b_2)j + (a_3 + b_3)k, \quad (2)$$

$$\lambda \dot{a} = (\lambda a_0) + (\lambda a_1)i + (\lambda a_2)j + (\lambda a_3)k,$$

and

$$\dot{a}\dot{b} = (a_0b_0 - a_1b_1 - a_2b_2 - a_3b_3) + (a_0b_1 + a_1b_0 + a_2b_3 - a_3b_2)i \quad (3)$$

$$+ (a_0b_2 - a_1b_3 + a_2b_0 + a_3b_1)j + (a_0b_3 + a_1b_2 - a_2b_1 + a_3b_0)k.$$

The conjugate and modulus of \dot{a} are defined by

$$\dot{a}^* = a_0 - a_1i - a_2j - a_3k, \quad (4)$$

$$|\dot{a}| = \sqrt{a_0^2 + a_1^2 + a_2^2 + a_3^2}.$$

In particular, a pure quaternion \dot{c} is defined as

$$\dot{c} = c_1i + c_2j + c_3k, \quad (5)$$

which means the real part of a pure quaternion is equal to zero. A quaternion matrix can be written as $\dot{D} = D_0 + D_1i + D_2j + D_3k \in \mathbb{H}^{m \times n}$. According to Eq. (1), we see that a quaternion has three imaginary parts. Since color images are consist of three color channels, we represent a color image as a pure quaternion matrix, with each pixel of an image considered as a pure quaternion (5). Suppose \dot{u} is a color image with quaternion matrix representation with three components (red, green, and blue). Mathematically, we indicate \dot{u} as

$$\dot{u} = u_r i + u_g j + u_b k, \quad (6)$$

where u_r , u_g , and u_b are the RGB channels of \dot{u} respectively. Every pixel of \dot{u} is a pure quaternion.

The identity quaternion matrix \dot{I} is the same as the classical identity matrix. For example, if $\dot{I} \in \mathbb{H}^{2 \times 2}$, then

$$\dot{I} = \begin{pmatrix} 1 + 0i + 0j + 0k & 0 + 0i + 0j + 0k \\ 0 + 0i + 0j + 0k & 1 + 0i + 0j + 0k \end{pmatrix}. \quad (7)$$

A square quaternion matrix is unitary if $\dot{D}^* \dot{D} = \dot{D} \dot{D}^* = \dot{I}$. The norms of quaternion matrices and vectors are defined as follows.

Definition 2.1. The ℓ_2 -norm of quaternion vector $\dot{a} = a_0 + a_1i + a_2j + a_3k \in \mathbb{H}^n$ is $\|\dot{a}\|_2 := \sqrt{\sum_i |a_i|^2}$; the ℓ_2 -norm of quaternion matrix is $\|\dot{D}\|_2 := \max(\sigma(\dot{D}))$, where $\sigma(\dot{D})$ is the set of singular values of \dot{D} , and the Frobenius norm is $\|\dot{D}\|_F := \sqrt{\sum_{i,j} |D_{i,j}|^2}$.

Definition 2.2. The norm $\|\dot{D}\|_2 = \sqrt{\text{tr}(\dot{D}^* \dot{D})}$, where $\text{tr}(\cdot)$ is the trace of matrix. $\text{tr}(D) = \sum_{i=1}^{\min(m,n)} \delta_i$, δ_i are the singular values of \dot{D} , $i = 1, 2, \dots, \min(m, n)$.

The singular value decomposition (SVD) of a quaternion matrix was proposed in [28] firstly.

Theorem 2.1. (Quaternion Singular Value Decomposition (QSVD))

Let $\dot{D} \in \mathbb{H}^{m \times n}$, then there exist two unitary quaternion matrices $\dot{U} \in \mathbb{H}^{m \times m}$ and $\dot{V} \in \mathbb{H}^{n \times n}$ such that $\dot{U} \dot{D} \dot{V}^* = \Sigma$, where $\Sigma = \text{diag}(\sigma_1, \sigma_2, \dots, \sigma_s)$, $\sigma_i \geq 0$ are the singular values of \dot{D} and $s = \min(m, n)$.

2.2. WNNM regularization

The weighted nuclear norm minimization (WNNM) method was first proposed by Gu et al. [25] for grayscale image denoising. Their model can be written as

$$\min_u \frac{\lambda}{2} \|u - z\|_2^2 + \|u\|_{w,*}, \quad (8)$$

where λ is a positive parameter, u is the ideal image, z is the observed image, and $\|\cdot\|_{w,*}$ denotes the weighted nuclear norm.

The model (8) has good performance in grayscale image denoising. Xie et al. gave the optimal solution of (8) [36]. Later, Gu et al. showed some applications of the WNNM method [23]. Due to the good performance and the existence of the optimal solution, the WNNM regularization was widely used in image processing. Ma et al. [37] combined the WNNM and total variation regularizer for grayscale image deblurring. Yair and Michaeli [38] applied the multi-scale strategy with WNNM for image restoration. [39] developed a model with a new data fidelity term to tackle mixed noise images.

All the aforementioned WNNM-based methods handle grayscale or color image restoration in a monochromatic way. In other words, they treat the three channels of the color image as three independent images and overlook the relationship between them. In this paper, we represent color images with pure quaternion matrices and extend the WNNM to the quaternion domain, which can better preserve the color structure and generate better color image restoration results.

3. Proposed model

In order to better preserve the inner-relationship of color channels, we represent the color image as a pure quaternion matrix. More specifically, suppose $\dot{u} \in \mathbb{H}^{m \times n}$ is a color image, the corresponding pure quaternion representation is as

$$\dot{u} = \begin{pmatrix} \dot{u}_{11}, \dot{u}_{12}, \dots, \dot{u}_{1n} \\ \dot{u}_{21}, \dot{u}_{22}, \dots, \dot{u}_{2n} \\ \vdots \\ \dot{u}_{m1}, \dot{u}_{m2}, \dots, \dot{u}_{mn} \end{pmatrix}, \quad (9)$$

where pure quaternion $\dot{u}_{ij} = \dot{u}_{ij}^r i + \dot{u}_{ij}^g j + \dot{u}_{ij}^b k$ denotes a pixel of \dot{u} , $i = 1, 2, \dots, m$, $j = 1, 2, \dots, n$, here \dot{u}_{ij}^r , \dot{u}_{ij}^g , and \dot{u}_{ij}^b are the red, green, and blue components, respectively. Suppose that $\dot{f} \in \mathbb{H}^{m \times n}$ is the observed image with quaternion representation, and $\dot{u} \in \mathbb{H}^{m \times n}$ is the ideal image with quaternion representation, our method can be written as follows

$$\min_{\dot{u}} \frac{\lambda}{2} \|\dot{A}\dot{u} - \dot{f}\|_2^2 + \|\dot{u}\|_{w,*}, \quad (10)$$

where \dot{A} is a linear operator with quaternion representation and $\|\cdot\|_{w,*}$ denotes the weighted nuclear norm. The weights w_i for the i th singular of \dot{u} follows the setting of WNNM [23] as

$$w_i = \frac{c}{\sigma_i + \epsilon}, \quad (11)$$

where c is a compromising constant, σ_i is the i th singular of \dot{u} , and ϵ is a small positive number.

Due to the blur operation and the weighted nuclear norm, it is not easy to directly solve model (10). Thanks to the alternating direction method of multipliers (ADMM) solver, our model can be handled and get the exact solution, so that the restoration results become more robust. By introducing the quaternion auxiliary variable $\dot{g} \in \mathbb{H}^{m \times n}$ and quaternion multiplier $\dot{\eta} \in \mathbb{H}^{m \times n}$ and letting $\dot{u} = \dot{g}$, the augmented Lagrangian of (10) is formulated by

$$\mathcal{L}(\dot{u}, \dot{g}; \dot{\eta}) = \min_{\dot{u}, \dot{g}, \dot{\eta}} \frac{\lambda}{2} \|\dot{A}\dot{u} - \dot{f}\|_2^2 + \|\dot{g}\|_{w,*} + \frac{\beta}{2} \|\dot{u} - \dot{g}\|_2^2 + \langle \dot{\eta}, \dot{u} - \dot{g} \rangle, \quad (12)$$

where $\beta > 0$ is a penalty parameter. The ADMM iteration for solving (12) goes as follows

$$\begin{cases} \dot{u}^{k+1} = \arg \min_{\dot{u}} \mathcal{L}(\dot{u}, \dot{g}^k; \dot{\eta}^k), \\ \dot{g}^{k+1} = \arg \min_{\dot{g}} \mathcal{L}(\dot{u}^{k+1}, \dot{g}; \dot{\eta}^k), \\ \dot{\eta}^{k+1} = \dot{\eta}^k + (\dot{u}^{k+1} - \dot{g}^{k+1}). \end{cases} \quad (13)$$

Table 1

$(\dot{\mu}\dot{u}^*\dot{v} + \dot{\tau})^2$	$-\frac{1}{2}\dot{g}\dot{\mu}\dot{v}^* - \frac{1}{2}\dot{\mu}(\dot{v}\dot{g})^*$	$\dot{g} = \dot{\mu}\dot{u}^*\dot{v} + \dot{\tau}$
$ \dot{\mu}\dot{u}\dot{v} + \dot{\tau} $	$\frac{\dot{g}^*}{2 \dot{g} }\dot{\mu}\Re(\dot{v}) - \frac{1}{4 \dot{g} }\dot{v}^*(\dot{\mu}^*\dot{g})^*$	$\dot{g} = \dot{\mu}\dot{u}\dot{v} + \dot{\tau}$
$ \dot{\mu}\dot{u}^*\dot{v} + \dot{\tau} $	$\frac{\dot{g}}{2 \dot{g} }\dot{v}^*\Re(\dot{\mu}^*) - \frac{1}{4 \dot{g} }\dot{\mu}(\dot{v}\dot{g}^*)^*$	$\dot{g} = \dot{\mu}\dot{u}^*\dot{v} + \dot{\tau}$
$ \dot{\mu}\dot{u}\dot{v} + \dot{\tau} ^2$	$\dot{g}^*\dot{\mu}\Re(\dot{v}) - \frac{1}{2}\dot{v}^*(\dot{\mu}^*\dot{g})^*$	$\dot{g} = \dot{\mu}\dot{u}\dot{v} + \dot{\tau}$
$ \dot{\mu}\dot{u}^*\dot{v} + \dot{\tau} ^2$	$\dot{g}\dot{v}^*\Re(\dot{\mu}^*) - \frac{1}{2}\dot{\mu}(\dot{v}\dot{g}^*)^*$	$\dot{g} = \dot{\mu}\dot{u}^*\dot{v} + \dot{\tau}$

Next, we elaborate on how to solve these subproblems respectively. The \dot{u} -subproblem is written as

$$\dot{u}^{k+1} = \arg \min_{\dot{u}} \frac{\lambda}{2} \|\dot{A}\dot{u} - \dot{f}\|_2^2 + \frac{\beta}{2} \|\dot{u} - \dot{g}^k\|_2^2 + \langle \dot{\eta}^k, \dot{u} - \dot{g}^k \rangle. \quad (14)$$

According to the theory of quaternion matrix derivatives [31] (here we list some required rules of quaternion matrix derivatives in Table 1), then the optimality condition of (14) is given by

$$\frac{\lambda}{2}(\dot{A}\dot{u} - \dot{f})^*\dot{A} - \frac{\lambda}{4}(\dot{A}^*(\dot{A}\dot{u} - \dot{f}))^* + \frac{\beta}{4} \left(\dot{u} - \dot{g}^k + \frac{\dot{\eta}^k}{\beta} \right)^* = 0, \quad (15)$$

where $(\cdot)^*$ denotes the conjugation operator. We can obtain the following linear system

$$(\lambda\dot{A}^*\dot{A} + \beta)\dot{u} = \lambda\dot{A}^*\dot{f} + \beta\dot{g}^k - \dot{\eta}^k. \quad (16)$$

Under the quaternion periodic boundary condition for \dot{u} , we know that $\dot{A}^*\dot{A}$ and $\dot{A}^*\dot{f}$ are block circulant, so the quaternion fast Fourier transform [30] can be used to find the solution of (16)

$$\dot{u}^{k+1} = \mathcal{F}^{-1} \left(\frac{\lambda\mathcal{F}(\dot{A})^* \circ \mathcal{F}(\dot{f}) + \beta\mathcal{F}(\dot{g}) - \mathcal{F}(\dot{\eta})}{\lambda\mathcal{F}(\dot{A})^* \circ \mathcal{F}(\dot{A}) + \beta} \right), \quad (17)$$

where \mathcal{F} denotes two-dimensional discrete quaternion Fourier transform, \mathcal{F}^{-1} represents two-dimensional discrete inverse quaternion Fourier transform, \circ means component-wise multiplication, and the division is component-wise as well.

The \dot{g} -subproblem is equivalent to

$$\dot{g}^{k+1} = \arg \min_{\dot{g}} \|\dot{g}\|_{w,*} + \frac{\beta}{2} \|\dot{g} - \left(\dot{u}^{k+1} + \frac{\dot{\eta}^k}{\beta} \right)\|_2^2. \quad (18)$$

Before solving the \dot{g} -subproblem, we first give the following theorems.

Theorem 3.1. For any $\dot{B} \in \mathbb{H}^{m \times n}$ (without loss of generality we assume that $m \geq n$) and a diagonal non-negative matrix $E \in \mathbb{R}^{m \times m}$, the diagonal elements e_i follows $e_1 \geq e_2 \geq \dots \geq e_n \geq 0$. Let $\dot{B} = \dot{X}\Phi\dot{Y}^*$, we have

$$\sum_{i=1}^n e_i t_i = \max_{\dot{U} \circ \dot{U}^* = I, \dot{V}^* \dot{V} = J} \text{tr}(E\dot{U}^*\dot{B}\dot{V}), \quad (19)$$

where t_i and e_i are the i th singular values of \dot{B} and E , respectively. When $\dot{U} = \dot{X}$ and $\dot{V} = \dot{Y}$, $\text{tr}(E\dot{U}^*\dot{B}\dot{V})$ reaches its maximum value.

Proof. Denote λ_i , $i = 1, 2, \dots, n$, are the singular values of $E\dot{U}^*\dot{B}\dot{V}$ with $\lambda_1 \geq \lambda_2 \geq \dots \geq \lambda_n \geq 0$.

$$\text{tr}(E\dot{U}^*\dot{B}\dot{V}) = \sum_{i=1}^n \lambda_i \leq \sum_{i=1}^n e_i t_i, \quad (20)$$

for $\dot{U} = \dot{X}$ and $\dot{V} = \dot{Y}$, $\text{tr}(E\dot{U}^*\dot{B}\dot{V})$ reaches its maximum value, i.e., Eq. (19) holds. \square

Theorem 3.2. For any $\dot{p} \in \mathbb{H}^{m \times n}$, the QSVD of \dot{p} is $\dot{p} = \dot{U}\dot{S}\dot{V}^*$, where

$$\dot{S} = \begin{pmatrix} \text{diag}(s_1, s_2, \dots, s_n) \\ 0 \end{pmatrix}. \quad (21)$$

According to (18), $\dot{p} = \dot{u} + \frac{\dot{\eta}}{\beta}$. The solution of \dot{g} -subproblem is $\dot{g} = \dot{U}\dot{K}\dot{V}^*$, where

$$\dot{K} = \begin{pmatrix} \text{diag}(k_1, k_2, \dots, k_n) \\ 0 \end{pmatrix}, \quad (22)$$

and (k_1, k_2, \dots, k_n) is the solution of the following convex optimization problem

$$\min_{k_1, \dots, k_n} \sum_{i=1}^n (k_i - s_i)^2 + w_i k_i, \quad \text{s.t. } k_1 \geq k_2 \geq \dots \geq k_n \geq 0. \quad (23)$$

Proof. For any $\dot{g} \in \mathbb{H}^{m \times n}$, according to Theorem 2.1, we have $\dot{g} = \dot{U}_1\dot{K}\dot{V}_1^*$ as the singular value decomposition of \dot{g} and

$$\dot{K} = \begin{pmatrix} \text{diag}(k_1, k_2, \dots, k_n) \\ 0 \end{pmatrix}, \quad (24)$$

with $k_1 \geq k_2 \geq \dots \geq k_n \geq 0$. From $\dot{p} = \dot{u} + \frac{\dot{\eta}}{\beta}$, we know that

$$\begin{aligned}
& \min_{\dot{g}} \|\dot{g}\|_{w,*} + \frac{\beta}{2} \|\dot{g} - (\dot{u} + \frac{\dot{\eta}}{\beta})\|_2^2 \\
\Leftrightarrow & \min_{\dot{g}} \|\dot{g}\|_{w,*} + \frac{\beta}{2} \|\dot{g} - \dot{p}\|_2^2 \\
\Leftrightarrow & \min_{\substack{\dot{U}_1, K, \dot{V}_1 \\ k_1 \geq k_2 \geq \dots \geq k_n \geq 0}} \|\dot{U}_1 K \dot{V}_1^*\|_{w,*} + \|\dot{p} - \dot{U}_1 K \dot{V}_1^*\|_2^2 \\
\Leftrightarrow & \min_{\substack{\dot{U}_1, K, \dot{V}_1 \\ k_1 \geq k_2 \geq \dots \geq k_n \geq 0}} \|K\|_{w,*} + \|\dot{p}\|_2^2 - |\text{tr}(\dot{p}^* \dot{U}_1 K \dot{V}_1^*)| - |\text{tr}(K \dot{U}_1^* \dot{V}_1)| + \|K\|_2^2 \\
\Leftrightarrow & \min_{\substack{\dot{U}_1, K, \dot{V}_1 \\ k_1 \geq k_2 \geq \dots \geq k_n \geq 0}} \|K\|_{w,*} - |\text{tr}(s \dot{U}_1^* \dot{U} K \dot{V}^* \dot{V}_1)| - |\text{tr}(K \dot{U}^* \dot{U}_1 S \dot{V}_1^* \dot{V})| + \|K\|_2^2 \\
\Leftrightarrow & \min_{k} \|K\|_{w,*} - \max_{\substack{(\dot{U}_1 \dot{U})^* (\dot{U}_1 \dot{U}) = I \\ (S \dot{V}_1^* S \dot{V}_1)^* = I}} (|\text{tr}(S(\dot{U}_1^* \dot{U}) K(\dot{V}^* \dot{V}_1))| + |\text{tr}(K(\dot{U}^* \dot{U}_1) S(\dot{V}_1^* \dot{V}))|) + \|K\|_2^2 \\
\Leftrightarrow & \min_{k_1 \geq k_2 \geq \dots \geq k_n \geq 0} \|K\|_{w,*} - \sum_{i=1}^n (s_i k_i + k_i s_i) + \|k\|_2^2 \\
\Leftrightarrow & \min_{k_1 \geq k_2 \geq \dots \geq k_n \geq 0} \sum_{i=1}^n w_i k_i - 2k_i s_i + k_i^2 \\
\Leftrightarrow & \min_{k_1 \geq k_2 \geq \dots \geq k_n \geq 0} \sum_{i=1}^n (k_i - s_i)^2 + w_i k_i.
\end{aligned} \tag{25}$$

From the above deduction, we can see that the solution of the \dot{g} -subproblem is

$$\dot{g} = \dot{U} K \dot{V}^*. \tag{26}$$

□

Then the minimization problem (12) has a unique solution and can be solved by the ADMM method. We can compute the solution of the \dot{u} subproblem according to Eq. (17). The process of our QWNNM algorithm is conclude in Algorithm 1. It is worth to

Algorithm 1 The proposed QWNNM algorithm.

Input:

Let $\dot{u}^0 = \dot{f}$, $\dot{g}^0 = \dot{u}^0$, $\dot{\eta}^0 = 0$;

Set parameters λ , β and w_i ;

Output:

The recovered image \dot{u}^k ;

1: **for** $k = 0$: kMax **do**

2: Calculate \dot{u}^{k+1} by Eq. (17);

3: Calculate \dot{g}^{k+1} by Eq. (26);

4: Update $\dot{\eta}^{k+1} = \dot{\eta}^k + (\dot{u}^{k+1} - \dot{g}^{k+1})$;

5: $k = k + 1$;

6: **end for**

mention that the blurring matrix \dot{A} and \dot{A}^* in (17) are not easy to handle. We synthesize a degraded image by using the Matlab built-in blurring kernels and then generate the corresponding blurring matrix. In the real number domain, the blurring matrix A is a monochromatic matrix. Since a quaternion matrix consists of three imaginary parts, how to generate a quaternion blurring matrix to solve \dot{u} is a big challenge. By filling the three imaginary parts of the quaternion with the same blurring matrix A , we define the quaternion blurring matrix \dot{A} as $\dot{A} = A_i + A_j + A_k$. We synthesize a degraded image by using the Matlab built-in blurring kernels and then generate the corresponding blurring matrix. For example, we use "H=fspecial('motion',20,60)" to create 2-D linear motion filter in Matlab and use the "padPSF" function in Matlab to pad an array with zeros to make it has the same dimension as the input image. Here the blur matrix is in real domain, however, we handle the color image restoration task in quaternion. Therefore, we generate

a quaternion blur matrix in quaternion domain as

$$\dot{A} = A_r i + A_g j + A_b = \begin{pmatrix} \dot{A}_{11}, \dot{A}_{12}, \dots, \dot{A}_{1n} \\ \dot{A}_{21}, \dot{A}_{22}, \dots, \dot{A}_{2n}, \\ \vdots \\ \dot{A}_{m1}, \dot{A}_{m2}, \dots, \dot{A}_{mn} \end{pmatrix}, \tag{27}$$

where $A_r = A_g = A_b = H$ and $\dot{A}_{ij} = A_{ij}^r i + A_{ij}^g j + A_{ij}^b k$ denotes a pixel of \dot{A} , here $i = 1, 2, \dots, m$ and $j = 1, 2, \dots, n$. The blur matrix \dot{A} here is a 2-D quaternion matrix. After applying the fast quaternion Fourier transform [30], the quaternion blurring matrix \dot{A} and \dot{A}^* can be expressed. In this fashion, all the elements in (17) can be computed in the quaternion domain and we can obtain the restoration result. The flowchart of the proposed method is displayed in Fig. 2. We first generate degradation images with blur and noise. Given the blurring kernel, we generate a blurring matrix corresponding to the original image. By applying the blurring kernel and adding noise to the original image, we synthesize a degraded color image. To solve the proposed model and better preserve the correlation of color channels, we transform the color image and the blurring matrix into the quaternion domain. By implementing the ADMM method and solving the \dot{u} , \dot{g} , and $\dot{\eta}$ subproblems, the recovery result is obtained.

Jia et al. [17] proposed a quaternion-based color image restoration model, which extended the classic TV model into the HSV color space, named SV-TV. Here we give some discussions between ST-TV and our QWNNM. Their SV-TV showed great success in color image restoration tasks, such as Gaussian noise removal, Gaussian blur with Gaussian noise restoration. However, they did not directly use the quaternion to represent the color image. Instead, they convert the quaternion into the HSV color space with the equation

$$\begin{cases} c_h(x, y) = \tan^{-1} \left(\frac{|u(x, y) - \mu u(x, y)v\mu|}{|u(x, y) - v u(x, y)v|} \right), \\ c_s(x, y) = \frac{1}{2} |u(x, y) + \mu u(x, y)\mu|, \\ c_v(x, y) = \frac{1}{2} |u(x, y) - \mu u(x, y)\mu|, \end{cases} \tag{28}$$

where $u(x, y) = u_0(x, y) + u_1(x, y)i + u_2(x, y)j + u_3(x, y)k$ is the color image, u_t are the real and imaginary parts of $u(x, y)$, $t = 0, 1, 2, 3$. Here μ referring to the gray-value axis, v is a unit

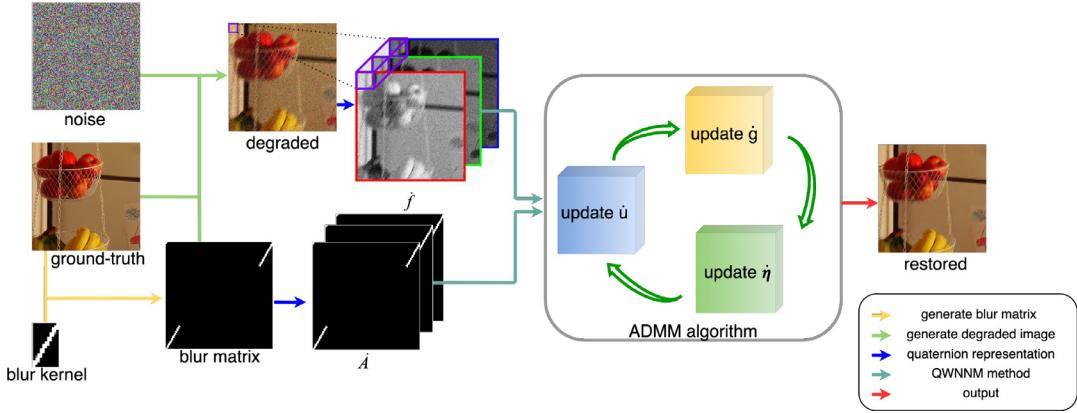

Fig. 2. The flowchart of the proposed method.

and pure quaternion number and ν is orthogonal to μ , and $c_h(x, y), c_s(x, y), c_\nu(x, y)$ are the HSV components, respectively. The main difference between the proposed method and SV-TV is the regularizer. While [17] utilized the SV-TV regularizer, the proposed method is based on the low rank regularizer, i.e., the effective WNNM regularizer. Due to the color information and structure, we extended the WNNM into the quaternion domain. Meanwhile, we studied the feasibility and the effectiveness of the proposed QWNM strategy. According to the strategy proposed in [17], they did not easily transform the RGB color space into the HSV color space, but creatively from Eq. (28). Besides, they claimed that the H-component does not contain a lot of image details like edges and developed a TV regularization in S and V channels in the HSV color space. Such a creative scheme generates great success in handling color images corrupted by the Gaussian blur and noise. Therefore, it is not fair to compare SV-TV with our work by directly transforming our QWNM into HSV color space. Here, we leave this work in the future.

4. Experiments

To demonstrate the effectiveness of the proposed model, we compare our method with several state-of-the-art methods for color image restoration, including LRTV [37], BM3D [40], SV-TV [17], MSWNNM [38], and the CNN-based method IRCNN [35]. We test with the images from Set27¹ and Set12², which are shown in Figs. 3 and 4, respectively. We test on three types of blur, “Gaussian”, “motion”, and “average”, for color image deblurring. We use the Matlab command “fspecial(‘gaussian’,25,1.6)”, “fspecial(‘motion’,20,60)”, and “fspecial(‘average’,9)” to generate the blurring kernels and add Gaussian white noise with Gaussian noise level (standard variance) $\sigma = 25$ to all images. In Matlab code, the fspecial (‘motion’, LEN,THETA) returns a filter to approximate, once convolved with an image, the linear motion of a camera by LEN pixels, with an angle of THETA degrees in a counter-clockwise di-

rection. The filter becomes a vector for horizontal and vertical motions.

4.1. Parameter setting

The parameters of the proposed model are: $\lambda = 60$, $\beta = 7.5$ for Gaussian blur with noise; $\lambda = 110$, $\beta = 7.5$ for motion blur with noise; $\lambda = 110$, $\beta = 8.5$ for average blur with noise. All compared methods are implemented with the available code and the default parameters mentioned in their corresponding paper. All the experiments are conducted under Windows10 and MATLAB R2019a running on a desktop (Intel(R) Core(TM) i9-9900 CPU @3.60 GHz and 16GB memory). IRCNN was proposed by Zhang et. al. [35] to tackle image restoration tasks, such as image denoising, deblurring, and super-resolution. In this paper, we focus on the image restoration task. Since IRCNN achieved very promising restoration results, we set the IRCNN method as one of our benchmarks. In this paper, the IRCNN network was implemented with MatConvNet toolbox and an NVIDIA GeForce RTX 2080Ti. It is worth stating that we did not retrain the IRCNN³. It is a coincidence that the test images of our method are mostly the same as the test set of IRCNN. IRCNN method performs well in Gaussian blur removal, however, since the type of blur is not only a standard Gaussian distribution but also motion and average distribution, the restored image will be undesirable. The termination criterion is defined as

$$\frac{\|\hat{u}^{i+1} - \hat{u}^i\|}{\|\hat{u}^{i+1}\|} < 10^{-4}, \quad (29)$$

where i is the number of iterations. After we get the result \hat{u} , we transform it into the real space as u^* and evaluate the quality. The peak signal to noise ratio (PSNR) and structural similarity (SSIM) [41] are chosen as the quantitative measure. They are defined by

$$\text{PSNR} = 20 \log_{10} \frac{255}{\frac{1}{mn} \|u^* - u\|_2}, \quad (30)$$

and

$$\text{SSIM}(u, u^*) = \frac{(2\mu_u\mu_{u^*} + C_1)(2\sigma_{uu} + C_2)}{(\mu_u^2 + \mu_{u^*}^2 + C_1)(\sigma_u^2 + \sigma_{u^*}^2 + C_2)}, \quad (31)$$

where u is the reference, μ_u , μ_{u^*} and σ_u , σ_{u^*} are the mean and the standard deviation of u and u^* , respectively. The positive constants C_1 and C_2 are used to avoid a null denominator.

In the experiments, we use the Matlab build-in function “psnr” and “ssim” to compute the PSNR and SSIM results. The higher the

Fig. 4. Images in Set12.

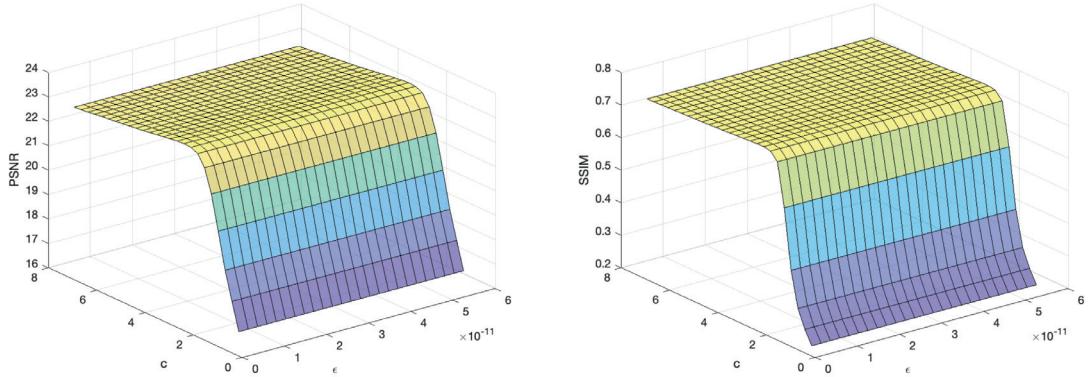

(a) PSNR values along with parameters c and ϵ .(b) SSIM values along with parameters c and ϵ .

Fig. 5. Parameter analysis of image 'Plane' under the motion blur and noise.

PSNR and SSIM are, the better the quality of the restored image is, and the SSIM value is between 0 and 1. The weight $w_i = \frac{c}{\sigma_i + \epsilon}$, where ϵ is a small number and c is a constant. We analyze the effectiveness of different ϵ and c . From Fig. 5, we can see the PSNR and SSIM curves of image 'Plane' with motion blur and noise along with ϵ and c . Here, ϵ is a small constant, we set it with the Matlab built-in function 'eps' as $\epsilon \in [1 : 250000] * \text{eps}$ with step size

10000. The parameter c in WNNM [25] was set to be $\sqrt{2}$, here we set $c \in [0.1 : 5] * \sqrt{2}$ with step size 0.2. As shown in Fig. 5, the parameter ϵ is a small positive constant to avoid the denominator as zero. Hence, ϵ does not effectively affect the results, we set $\epsilon = \text{eps}$ for all our experiments. Meanwhile, c is a significant parameter in the weight w_i . The choice of c is directly affecting the weight w_i

(a) original image, (b) degraded image with motion kernel (20, 60) and Gaussian noise level $\sigma = 25$, restored image reconstructed by: (c) LRTV [37], (d) BM3D [40], (e) SV-TV [17], (f) MSWNNM [38], (g) IRCNN [35], (h) our QWNNM.

and the final result. Through trial and error, we set $c = 1.7 * \sqrt{2}$ for all our experiments.

4.2. Restoration results

The PSNR and SSIM values of compared restoration methods with Gaussian blur $GB(25, 1.6)/\sigma = 25$ is shown in Table 2, The corresponding results with motion blur $MB(20, 60)/\sigma = 25$ and with average blur $AB(9, 9)/\sigma = 25$ are shown in Tables 3 and 4,

respectively. We highlight the best results in bold and underline the second-best results. From the numerical results, we see that the proposed method generates better restoration results with different types of blur. We also display the restoration images to demonstrate the visual quality of the proposed method. Figs. 6, 7 and 8 are the restoration results of images degraded by Gaussian blur and noise. The color spots are still visible in the results of LRTV [37] and MSWNNM [38], which are the WNNM-

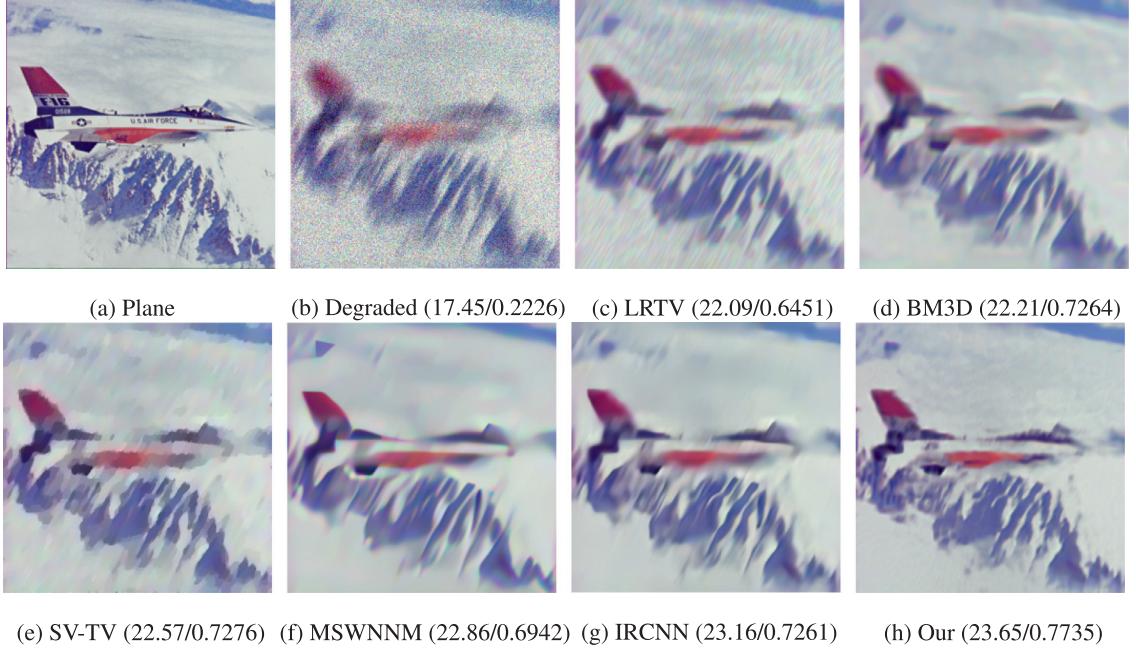

Fig. 11. Color image restoration on 'Plane' with visual quality and numerical results (PSNR/SSIM). (a) original image, (b) degraded image with motion kernel (20, 60) and Gaussian noise level $\sigma = 25$, restored image reconstructed by: (c) LRTV [37], (d) BM3D [40], (e) SV-TV [17], (f) MSWNNM [38], (g) IRCNN [35], (h) our QWNNM.

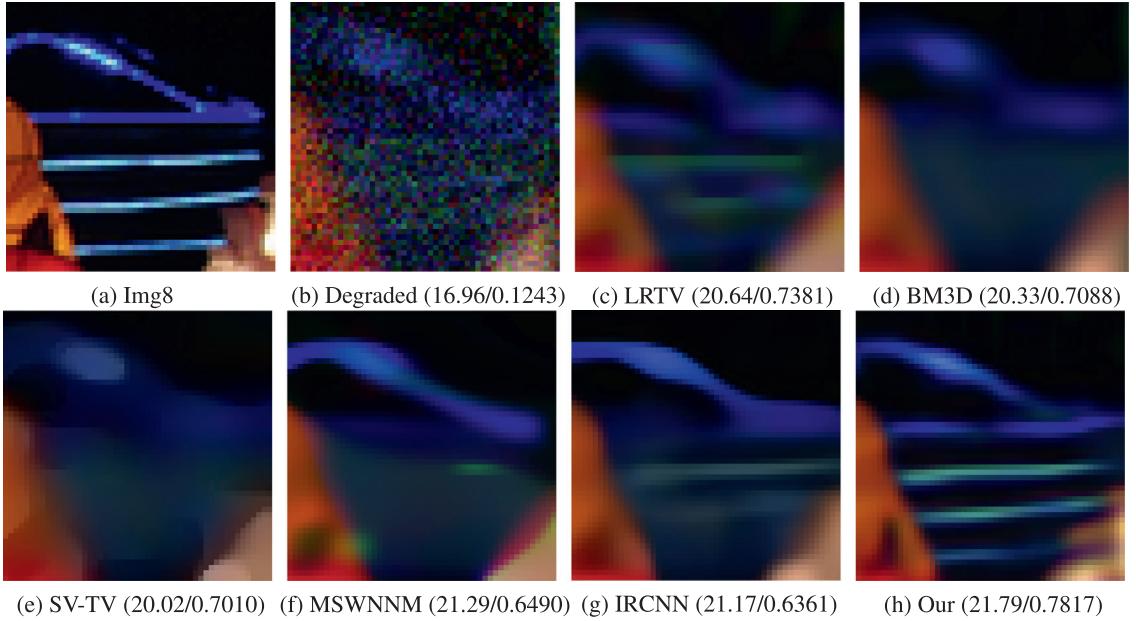

Fig. 12. Zoom in part of color image restoration on Img8 with visual quality and numerical results (PSNR/SSIM). (a) original image, (b) degraded image with average kernel (9, 9) and Gaussian noise level $\sigma = 25$, restored image reconstructed by: (c) LRTV [37], (d) BM3D [40], (e) SV-TV [17], (f) MSWNNM [38], (g) IRCNN [35], (h) our QWNNM.

based method in the real number domain. The blur seems not to be removed fully in the restored images of BM3D [40]. The SV-TV [17] is a quaternion-based method, which can generate good results in low Gaussian noise level. However, with Gaussian noise level $\sigma = 25$, the restoration results seem not so good. We also compared our method with the IRCNN [35], which is a convolutional neural network method. From the visual results, we observe that the proposed method can better preserve the color structure of the color channels. Figs. 9, 10, and 11 are the results of restoration with motion blur and noise. In Fig. 9, we see that the pro-

posed method can better preserve the detailed information. For Fig. 10, the zoom-in part of the original image is a flower from the lower right corner to the upper left corner, and the degradation we added is motion blur moving to the right. For Fig. 11, even the mount below the plane is in the same direction with the motion blur, the restoration of our QWNNM still has the best result. It is not difficult to see from the degradation diagram that degradation is quite severe. Compared with the results of other methods, only our method can show the real shape of the image. Figs. 12, 13, and 14 are the restoration results of average blur with noise.

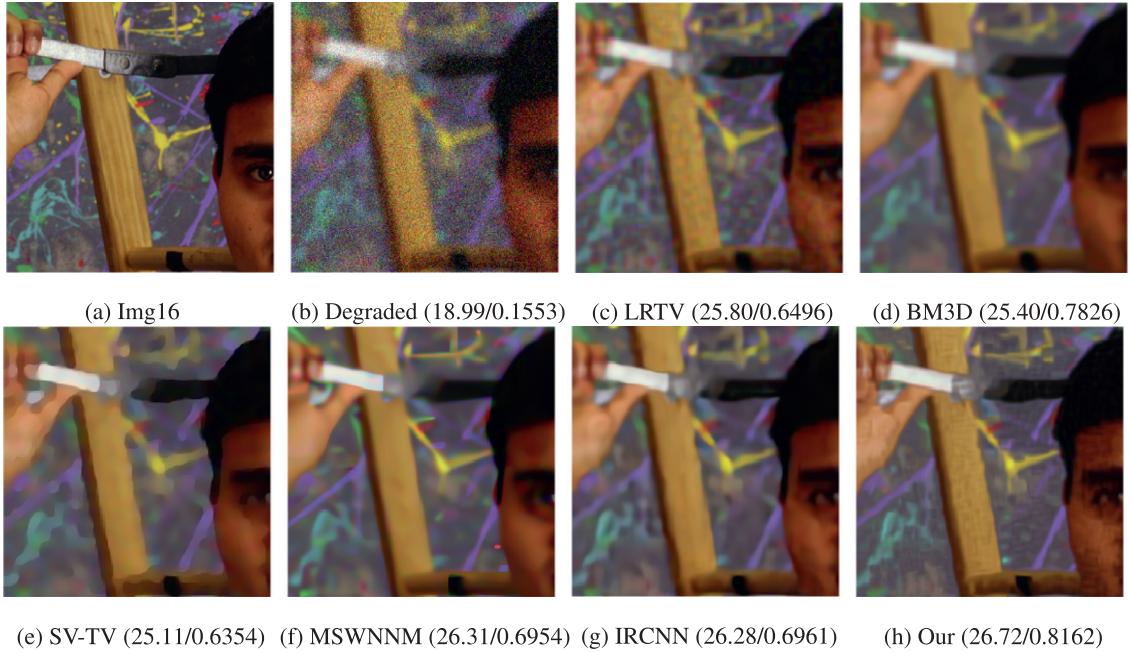

Fig. 13. Zoom in part of color image restoration on Img16 with visual quality and numerical results (PSNR/SSIM). (a) original image, (b) degraded image with average kernel (9, 9) and Gaussian noise level $\sigma = 25$, restored image reconstructed by: (c) LRTV [37], (d) BM3D [40], (e) SV-TV [17], (f) MSWNNM [38], (g) IRCNN [35], (h) our QWNNM.

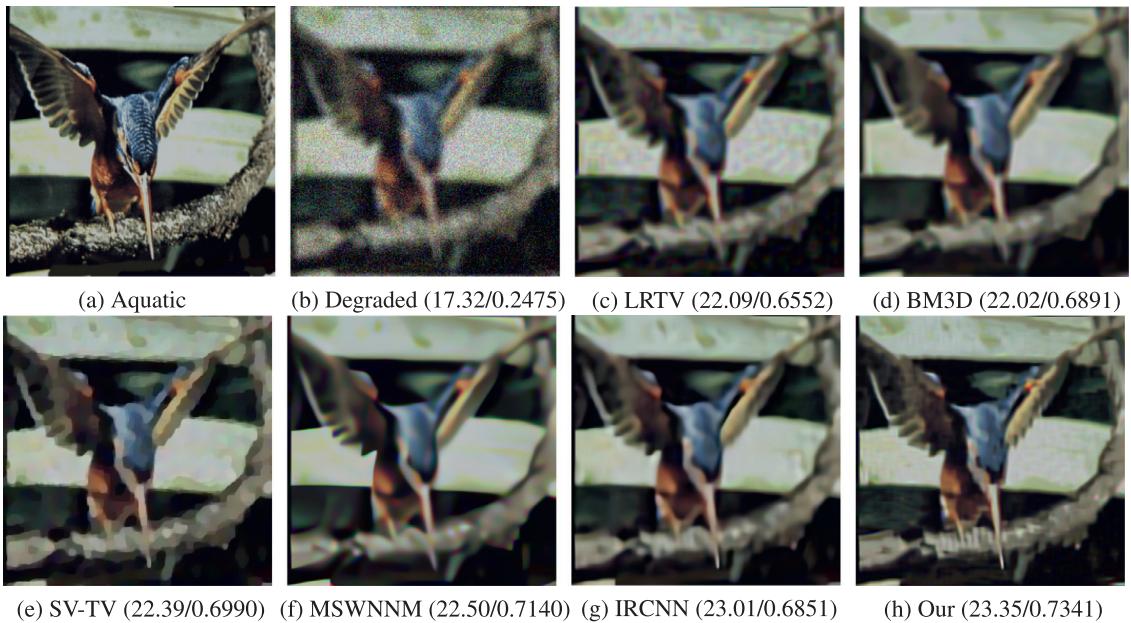

Fig. 14. Color image restoration on ‘Aquatic’ with visual quality and numerical results (PSNR/SSIM). (a) original image, (b) degraded image with average kernel (9, 9) and Gaussian noise level $\sigma = 25$, restored image reconstructed by: (c) LRTV [37], (d) BM3D [40], (e) SV-TV [17], (f) MSWNNM [38], (g) IRCNN [35], (h) our QWNNM.

From Fig. 12, we observe that the detailed structures of our restored color images are better than the others. In the background of Fig. 13, we can see that the color distribution is avoided by our method. From Fig. 14, we know that compared with other restoration methods, our QWNNM can better prevent the oversmoothing and recover the detailed structure of the image. From all test images, we see that the proposed method has the best performance in both visual quality and numerical results.

To better demonstrate the advantages of the proposed method in color image restoration, we use the S-CIELAB error⁴ to analyze

the color quality of all compared methods in Fig. 15. We set the S-CIELAB error from 0 to 80 to study the number of error pixels between the original image and the restored image. The S-CIELAB error is used to evaluate the error between a pair of images that are presently coded as RGB data. We input the original image and the restored image as a pair and evaluate the S-CIELAB error from 0 to 80. We plot the S-CIELAB error of all the test images with the three different blur. The curves show that the proposed method has the least error pixels when the S-CIELAB error is zero and when the curves converge.

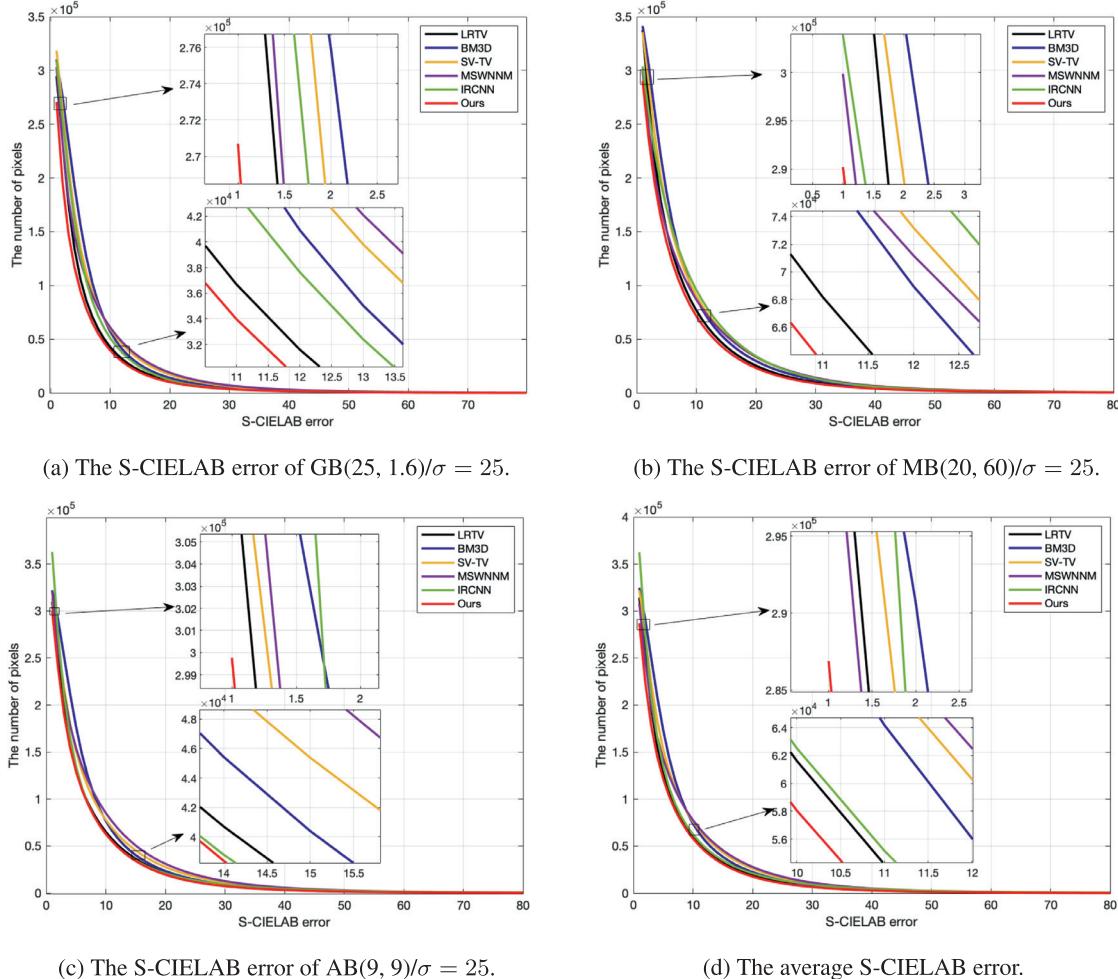

Fig. 15. The S-CIELAB error of all compared methods on Set27. (a) the average S-CIELAB error of all degraded images with $GB(25, 1.6)/\sigma = 25$, (b) the average S-CIELAB error of all degraded images with $MB(20, 60)/\sigma = 25$, (c) the average S-CIELAB error of all degraded images with $AB(9, 9)/\sigma = 25$, (d) the average S-CIELAB error of all test images and all blur types.

5. Conclusions

In this paper, we proposed and analyzed a quaternion-based model for color image restoration, which can overcome the disadvantages of existing real-valued WNNM-based methods. We represented the color image with a pure quaternion matrix and applied the classical WNNM method in the quaternion domain. Hence, the correlation of color channels can be well preserved. Due to the special multiplication and derivation rules of the quaternion, the mathematical deduction of the weighted nuclear norm is different from the real-valued deduction. Therefore, we carefully designed a blurring operator in the quaternion domain and proved the uniqueness of the optimal solution. In three types of blur kernels with noise, our QWNNM method generated better restoration results, which demonstrate the robustness of the proposed model. Both visual and numerical results on two different datasets illustrated the robustness of the proposed scheme. Compared with both the real-valued traditional and convolutional neural network methods, our quaternion-based method can better preserve the color structure and avoid color distribution. However, the proposed strategy has its limitations. We applied the classical ADMM solver to handle our QWNNM model, in fact, there is a more accurate solution for the proposed convex problem. Later on, we plan to design a more advanced algorithm to improve the accuracy of the solution.

Chaoyan Huang received the BS degree in College of Mathematics and Computer Science from the Anqing Normal University, Anqing, China, in 2019. She is currently pursuing the MS degree with the School of Science, Nanjing University of Posts and Telecommunications, Nanjing, China. Her research interests include image processing and machine learning.

Zhi Li received the BS degree and the MS degree from China University of Petroleum, Shandong, China, in 2007 and 2010, respectively. He also received the MS degree in applied science from Saint Mary's University, Halifax, NS, Canada, in 2012. After being awarded the Hong Kong PhD Fellowship, he went to Hong Kong Baptist University, Hong Kong, where he received the PhD degree in 2016. Then he worked as a Postdoctoral Researcher at Michigan State University, East Lansing, MI, USA, from 2016 to 2019. He is currently an associate researcher with the Department of Computer Science and Technology, East China Normal University, Shanghai, China.

Yubing Liu is currently pursuing his BS degree with Bell Honor School, Nanjing University of Posts and Telecommunications, Nanjing, China. His research interests include image processing, computer vision, and machine learning.

Tingting Wu is currently an Associate Professor in the School of Science, Nanjing University of Posts and Telecommunications, Nanjing, China. She received the BS and PhD degrees in mathematics from Hunan University, Changsha, China, in 2006 and 2011, respectively. In 2015–2018, she was a Post-Doctoral Researcher with the School of Mathematical Sciences, Nanjing Normal University, Nanjing, China. In 2016–2017, she was a Research Fellow in Nanyang Technological University, Singapore. Her research interests include variational methods for image processing and computer vision, optimization methods and their applications in sparse recovery and regularized inverse problems.

Tieyong Zeng is currently a Professor in the Department of Mathematics, The Chinese University of Hong Kong. He received the BS degree from Peking University, Beijing, China, the MS degree from Ecole Polytechnique, Palaiseau, France, and the PhD degree from the University of Paris XIII, Paris, France, in 2000, 2004, and 2007, respectively. His research interests include image processing, optimization, artificial intelligence, scientific computing, computer vision, machine learning, and inverse problems.
